[P385-2016] “Analytic and Experimental Analysis of Magnetic Force Equations”
Gama, S.; Ferreira, L. D. R.; Bessa, C. V. X.; Horikawa, O.; Coelho, A. A.*; Gandra, F. C.*; Araujo, R.; Egolf, P. W.
The design of magnetic devices requires a precise estimation of magnetic forces. In previous works, we presented a general approach to estimate these forces based upon thermodynamically closed systems, resulting in four different forms of the force equations. This paper presents a complete theoretical model analysis tested by experiments, using arrangements of permanent magnets and a device for measuring the force induced on a soft magnetic material according to its position with respect to the permanent magnets. The results of analytical formulation, Finite Element Method numerical analysis, and experiments are compared with each other. This enabled the identification of two forms of the force equations that most precisely describe the magnetic forces. A follow-up experiment is then proposed and executed, identifying the correct form of the magnetic force equations. The resulting equation can be used to analytically estimate the magnetic force in many practical problems.

[P386-2016] “Architecting new diffraction-resistant light structures and their possible applications in atom guidance”
Pachon, E. G. P.*; Zamboni-Rached, M.*; Dorrah, A. H.; Mohajedi, M.; Gesualdi, M. R. R.; Cabrera, G. G.*
In this work we extend the so-called frozen wave method in order to obtain new diffraction resistant light structures that can be shaped on demand, with possible applications in atom guidance. The resulting beams and the corresponding optical dipole potentials exhibit a strong resistance to diffraction effects and their longitudinal and transverse intensity patterns can be chosen a priori. Besides the theoretical development, we also present the experimental confirmation of our approach; specifically, by generating three different beam profiles using a spatial light modulator that is addressed by a computer-generated hologram. In addition to its many potential applications in atom guiding, the method developed here can also lead to many new developments in optics and photonics in general.

DarkSide Collaboration
DarkSide-50 is a dark matter direct search experiment at LNGS, searching for rare nuclear recoils possibly induced by WIMPs. It has two nested vetoes and a dual phase liquid argon TPC as dark matter detector. Key features of this experiment are the use of underground argon as radio-pure target and of muon and neutron active vetoes to suppress the background. The first data-taking campaign was running from November 2013 to April 2015 with an atmospheric argon target and a reduced efficiency neutron veto due to internal contamination. However, an upper limit on the WIMP-nucleon cross section of 6.1x10(-44) cm(2) at 90% CL was obtained for a WIMP mass of 100 GeV/c(2) and an exposure of (1422 +/- 67) kg.d. At present DarkSide-50 started a 3 years run, intended to be background-free because the neutron veto was successfully recovered and underground argon replaced the atmospheric one. Additionally calibration campaigns for both the TPC and the neutron veto were completed. Thanks to the good performance of the background rejection, the results obtained so far suggest the scalability of DarkSide-50 to a ton-scale detector, which will play a key role into the dark matter search scenario.

Synchrotron-radiation-based X-ray imaging techniques using tender X-rays are facing a growing demand, in particular to probe the K absorption edges of low-Z elements. Here, a mathematical model has been developed for estimating the detective quantum efficiency (DQE) at zero spatial frequency in the tender X-ray energy range for photon-counting detectors by taking into account the influence of electronic noise. The experiments were carried out with a Medipix3RX ASIC bump-bonded to a 300 mm silicon sensor at the Soft X-ray Spectroscopy beamline (DDA-SXS) of the Brazilian Synchrotron Light Laboratory (LNLS, Campinas, Brazil). The results show that Medipix3RX can be used to develop new imaging modalities in the tender X-ray range for energies down to 2 keV. The efficiency and optimal DQE depend on the energy and flux of the photons. The optimal DQE values were found in the 7.9-8.6 keV photon energy range. The DQE deterioration for higher energies due to the lower absorption efficiency of the sensor and for lower energies due to the electronic noise has been quantified. The DQE for 3 keV photons and 1 x 10(4) photons pixel(-1) s(-1) is similar to that obtained with 19 keV photons. Based on our model, the use of Medipix3RX could be extended down to 2 keV which is crucial for coming applications in imaging techniques at modern synchrotron sources.

[P389-2016] “Higher harmonic flow coefficients of identified hadrons in Pb-Pb collisions at root sNN=2.76 TeV”
ALICE Collaboration
The elliptic, triangular, quadrangular and pentagonal anisotropic flow coefficients for pi(+-), K(+-) and p+p in Pb-Pb collisions at root sNN = 2.76 TeV were measured with the ALICE detector at the Large Hadron Collider. The results were obtained with the Scalar Product method, correlating the identified hadrons with reference particles from a different pseudorapidity region. Effects not related to the common event conditions generated by A Multi-Phase Transport model (AMPT)
and describes the expansion of the fireball using a value of 0.08 for the ratio of shear viscosity to entropy density (eta/s), coupled to a hadronic cascade model (UrQMD). Finally, expectations from AMPT alone fail to quantitatively describe the measurements for all harmonics throughout the measured transverse momentum region. However, the comparison to the AMPT model highlights the importance of the late hadronic rescattering stage to the development of the observed mass ordering at low values of pT and of coalescence as a particle production mechanism for the particle type grouping at intermediate values of pT for all harmonics.

[P390-2016] “Influence of substrate pre-treatments by Xe+ ion bombardment and plasma nitriding on the behavior of TiN coatings deposited by plasma reactive sputtering on 100Cr6 steel”

Vales, S.; Brito, P.; Pineda, F. A. G.; Ochoa, E. A. *; Droppa, R.; Garcia, J.; Morales, M. *; Alvarez, F. *; Pinto, H.

In this paper the influence of pre-treating a 100Cr6 steel surface by Xe+ ion bombardment and plasma nitriding at low temperature (380 degrees C) on the roughness, wear resistance and residual stresses of thin TiN coatings deposited by reactive IBAD was investigated. The Xe+ ion bombardment was carried out using a 1.0 keV kinetic energy by a broad ion beam assistance. The results showed that in the studied experimental conditions the ion bombardment intensifies nitrogen diffusion by creating lattice imperfections, stress, and increasing roughness. In case of the combined pre-treatment with Xe+ ion bombardment and subsequent plasma nitriding, the samples evolved relatively high average roughness and the wear volume increased in comparison to the substrates exposed to only nitriding or ion bombardment.

[P392-2016] “Neutrino decay and solar neutrino seasonal effect”

Picoreti, R. *; Guzzo, M. M. *; de Holanda, P. C. *; Peres, O. L. G. *

We consider the possibility of solar neutrino decay as a sub-leading effect on their propagation between production and detection. Using current oscillation data, we set a new lower bound to the nu(2) neutrino lifetime at tau(2)/(m(2)) > 7.2 x 10(-4) s.eV(-1) at 99% C.L. Also, we show how seasonal variations in the solar neutrino data can give interesting additional information about neutrino lifetime.

[P393-2016] “Search for new physics in final states with two opposite-sign, same-flavor leptons, jets, and missing transverse momentum in pp collisions at TeV”

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. *; Tonelli Mangnute, E. J. *; et al.

A search is presented for physics beyond the standard model in final states with two opposite-sign, same-flavor leptons, jets, and missing transverse momentum. The data sample corresponds to an integrated luminosity of 2.3 fb(-1) of proton-proton collisions at TeV collected with the CMS detector at the LHC in 2015. The analysis uses the invariant mass of the lepton pair, searching for a kinematic edge or a resonant-like excess compatible with the Z boson mass. Both search modes use several event categories in order to increase the sensitivity to new physics. These categories are based on the rapidity of the leptons, the multiplicity of jets and b jets, the scalar sum of jet transverse momenta, and missing transverse momentum. The observations in all signal regions are consistent with the expectations from the standard model, and the results are interpreted in the context of simplified models of supersymmetry.

[P394-2016] “Search for supersymmetry in pp collisions at root s=13 TeV in the single-lepton final state using the sum of masses of large-radius jets”

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. *; Tonelli Mangnute, E. J. *; et al.

CMS Collaboration

Results are reported from a search for supersymmetric particles in proton-proton collisions in the final state with a single, high transverse momentum lepton; multiple jets, including at least one b-tagged jet; and large missing transverse momentum. The data sample corresponds to an integrated luminosity of 2: 3 fb(-1) at root s = 13 TeV, recorded by the CMS experiment at the LHC. The search focuses on processes leading to high jet multiplicities, such as gluino pair production with (g) over bar(chi) over tilde (0)(1). The quantity M-J, defined as the sum of the masses of the large-radius jets in the event, is used in conjunction with other kinematic variables to provide discrimination between signal and background and as a key part of the background estimation method.
The observed event yields in the signal regions in data are consistent with those expected for standard model backgrounds, estimated from control regions in data. Exclusion limits are obtained for a simplified model corresponding to gluino pair production with three-body decays into top quarks and neutralinos. Gluinos with a mass below 1600 GeV are excluded at a 95% confidence level for scenarios with low (chi) over tilde (0(1)) mass, and neutralinos with a mass below 800 GeV are excluded for a gluino mass of about 1300 GeV. For models with two-body gluino decays producing on-shell top squarks, the excluded region is only weakly sensitive to the top squark mass.

JOURNAL OF HIGH ENERGY PHYSICS [8], 122, 2016. DOI: 10.1007/JHEP08(2016)122

[P395-2016] “Searches for R-parity-violating supersymmetry in pp collisions at root s=8 TeV in final states with 0-4 leptons”
Khachatryan, V.; Sirunyan, A. M.; Chinellato, J.*; Tonelli Mangano, E. J.*; et al.
CMS Collaboration

Results are presented from searches for R-parity-violating supersymmetry in events produced in pp collisions at root s = 8 TeV at the LHC. Final states with 0, 1, 2, or multiple leptons are considered independently. The analysis is performed on data collected by the CMS experiment corresponding to an integrated luminosity of 19.5 fb(-1). No excesses of events above the standard model expectations are observed, and 95% confidence level limits are set on supersymmetric particle masses and production cross sections. The results are interpreted in models featuring R-parity-violating decays of the lightest supersymmetric particle, which in the studied scenarios can be either the gluino, a bottom squark, or a neutralino. In a gluino pair production model with baryon number violation, gluinos with a mass less than 0.98 and 1.03 TeV are excluded, by analyses in a fully hadronic and one-lepton final state, respectively. An analysis in a dilepton final state is used to exclude bottom squarks with masses less than 307 GeV in a model considering bottom squark pair production. Multilepton final states are considered in the context of either strong or electroweak production of superpartners and are used to set limits on the masses of the lightest supersymmetric particles. These limits range from 300 to 900 GeV in models with leptonic and up to approximately 700 GeV in models with semileptonic R-parity-violating couplings.

[P396-2016] “Upsilon (nS) polarizations versus particle multiplicity in pp collisions at root s=7 TeV”
Khachatryan, V.; Sirunyan, A. M.; Chinellato, J.*; Tonelli Mangano, E. J.*; et al.
CMS Collaboration

The polarizations of the Upsilon(1S), Upsilon(2S), and Upsilon(3S) mesons are measured as a function of the charged particle multiplicity in proton-proton collisions at root s = 7 TeV. The measurements are performed with a dimuon data sample collected in 2011 by the CMS experiment, corresponding to an integrated luminosity of 4.9 fb(-1). The results are extracted from the dimuon decay angular distributions, in two ranges of Upsilon(nS) transverse momentum (10-15 and 15-35 GeV), and in the rapidity interval \(|y| < 1.2\). The results do not show significant changes from low- to high-multiplicity pp collisions, although large uncertainties preclude definite statements in the Upsilon(2S) and Upsilon(3S) cases.

[P397-2016] “Simulation and Fabrication of Silicon Nitride Microring Resonator by DUV Lithography”
IEEE

This work reports the design and fabrication of silicon nitride-based microresonators by employing DUV optical lithography and ICP-RIE plasma etching. Microring devices with high Q factors provide high sensitivity and low detection limit, enabling their use in biochemical sensing applications. With these properties, the devices can be used to detect and quantify the biomolecules present in a homogeneous solution, by detecting an effective refractive index change, without using fluorescent labels.

[P398-2016] “THz Solar Observations on Board of a Trans-Antarctic Stratospheric Balloon Flight”
IEEE

A new system of two photometers was built to observe the Sun at 3 and 7 THz from space, named SOLAR-T. It has been flown coupled to U.C. Berkeley GRIPS experiment on a NASA stratospheric balloon flight over Antarctica, 19-30 January 2016. The mission was successfully accomplished. We describe the system performance, solar brightness determination and the first THz impulsive burst detected.

IEEE

In this work we used an atmospheric pressure dielectric barrier discharge plasma to perform treatments of poly(dimethylsiloxane) (PDMS) surfaces in order to improve the adhesion between the samples. The results show that different conditions of plasma treatment can lead to a better adhesion between the PDMS surfaces. If the power delivered to the plasma is increased, the adhesion is better, but the best results are obtained if the vibrational temperature of the nitrogen molecules in the plasma is increased.

2016 31ST SYMPOSIUM ON MICROELECTRONICS TECHNOLOGY AND DEVICES (SBMICRO), 2016.
A new type of magnetocaloric composite based on conductive polymer and magnetocaloric compound

Imamura, W.; Coelho, A. A.; Kupfer, V. L.; Carvalho, A. M. G.; Zago, J. G.; Rinaldi, A. W.; Favaro, S. L.; Alves, C. S.

We introduce a processing route of the first magnetocaloric composite with conductive polymer - wherein the magnetocaloric reinforcement is a compound Gd5.09Ge2.03Si1.88 and the ductile matrix is a conductive polymer polyaniline doped by camphorsulfonic acid (PAni-CSA). This new type of composite combines mechanical, electrical and magnetocaloric properties that can be applied in thermomagnetic machines.

A simple capacitive method to evaluate ethanol fuel samples

Ethanol is a biofuel used worldwide. However, the presence of excessive water either during the distillation process or by fraudulent adulteration is a major concern in the use of ethanol fuel. High water levels may cause engine malfunction, in addition to being considered illegal. Here, we describe the development of a simple, fast and accurate platform based on nanostructured sensors to evaluate ethanol samples. The device fabrication is facile, based on standard microfabrication and thin-film deposition methods. The sensor operation relies on capacitance measurements employing a parallel plate capacitor containing a conformational aluminum oxide (Al2O3) thin layer (15 nm). The sensor operates over the full range water concentration, i.e., from approximately 0% to 100% vol. of water in ethanol, with water traces being detectable down to 0.5% vol. These characteristics make the proposed device unique with respect to other platforms. Finally, the good agreement between the sensor response and analyses performed by gas chromatography of ethanol biofuel endorses the accuracy of the proposed method. Due to the full operation range, the reported sensor has the technological potential for use as a point-of-care analytical tool at gas stations or in the chemical, pharmaceutical, and beverage industries, to mention a few.

SCIENTIFIC REPORTS 7, 43432, 2017. DOI: 10.1038/srep43432

A Targeted Search for Point Sources of EeV Photons with the Pierre Auger Observatory

Simultaneous measurements of air showers with the fluorescence and surface detectors of the Pierre Auger Observatory allow a sensitive search for EeV photon point sources. Several Galactic and extragalactic candidate objects are grouped in classes to reduce the statistical penalty of many trials from that of a blind search and are analyzed for a significant excess above the background expectation. The presented search does not find any evidence for photon emission at candidate sources, and combined p-values for every class are reported. Particle and energy flux upper limits are given for selected candidate sources. These limits significantly constrain predictions of EeV photon emission models from non-transient Galactic and nearby extragalactic sources, as illustrated for the particular case of the Galactic center region.

Ag Nanoparticles-Based Zinc Hydroxide-Layered Hybrids as Novel and Efficient Catalysts for Reduction of 4-Nitrophenol to 4-Aminophenol

Silver nanoparticles and zinc hydroxide-layered hybrid materials (AgNPs/ZHL) have been successfully developed as efficient catalysts for the reduction of 4-nitrophenol (4-NP) to 4-aminophenol (4-AP) with sodium borohydride. A facile and rapid visible-light assisted green route was used for the deposition of silver nanoparticles (AgNPs) on the external surface of ZHL material. The resulting AgNPs/ZHL hybrids contained AgNPs with spherical morphology and uniform size distribution. Moreover, the AgNPs/ZHL compounds exhibited excellent catalytic performance (the reduction reaction was finished within 4 min) and reusability (three cycles) toward the reduction of 4-NP to 4-AP in presence of sodium borohydride. The reduction reaction obeyed the pseudo-first-order kinetics. The rate constants increased with the increase of amount of the AgNPs deposited into the hybrid materials. These results suggest that the as-prepared catalysts (AgNPs/ZHL) have great potential for heterogeneous catalytic applications.

However, if populations are confined to narrow ranges by geographic barriers, ring species formation increases when local mating is less spatially restricted. Ring species are most likely to form if a population expands while confined to a quasi-unidimensional range but preserving high mobility in the direction of the range expansion. These conditions are unlikely to be met or persist in real populations and may explain why ring species are rare.

**[P014-2017] “Bragg gratings in surface-core fibers: Refractive index and directional curvature sensing”**

Olorio, J. H.‡; Oliveira, R.*; Aristilde, S.*; Chesini, G.*; Franco, M. A. R.; Nogueira, R. N.; Cordeiro, C. M. B.*

In this paper, we report, to our knowledge, the first extended study of the inscription of Bragg gratings in surface-core fibers and their application in refractive index and directional curvature sensing. The research ranges from fiber fabrication and grating inscription in unclad and tapered fibers to the performance of simulations and sensing measurements. Maximum sensitivities of 40 nm/RIU and 202.7 pm/m (1) were attained in refractive index and curvature measurements respectively. The obtained results compares well to other fiber Bragg grating based devices. Ease of fabrication, robustness and versatility makes surface-core fibers an interesting platform when exploring fiber sensing devices.

**OPTICAL FIBER TECHNOLOGY 34, 86-90, 2017. DOI: 10.1016/j.yotfe.2017.01.007**

Espinell, Y. A. V.*; Santos, F. G. S.*; Luiz, G. O.*; Alegre, T. P.*; Wiederhecker, G. S.*

The simultaneous control of optical and mechanical waves has enabled a range of fundamental and technological breakthroughs, from the demonstration of ultra-stable frequency reference devices, to the exploration of the quantum-classical boundaries in optomechanical laser-cooling experiments. More recently, such an optomechanical interaction has been observed in integrated nano-waveguides and microcavities in the Brillouin regime, where short-wavelength mechanical modes scatter light at several GHz. Here we engineer coupled optical microcavities to enable a low threshold excitation of mechanical travelling-wave modes through backward stimulated Brillouin scattering. Exploring the backward scattering we propose silicon microcavity designs based on laterally coupled single and double-layer cavities, the proposed structures enable optomechanical coupling with very high frequency modes (11 to 25 GHz) and large optomechanical coupling rates (g(0)/2 pi) from 50 kHz to 90 kHz.

**[P016-2017] “Building block magneto-luminescent nanomaterials of iron-oxide/ZnS@LaF3:Ce3+,Gd3+,Tb3+ with green emission”**

The preparation of novel triply-doped bifunctional Fe3O4/ZnS@LaF3:Ce3+,Gd3+,Tb3+ (x = 5; y = 5, 10 and 15 mol%) nanocomposites with efficient optical and magnetic features has been reported. The ZnS semiconductor functionalized Fe3O4 particles were coated with LaF3:RE3+ materials via a chitosan-assisted co-precipitation method. The size of iron oxide similar to 7.2 nm and trigonal structures of bifunctional nanostructures were confirmed through X-ray diffraction and high-resolution transmission electron microscopy. The static magnetic measurements supported and manifested the superparamagnetic behavior of the materials at 300 K. A broad emission band was observed in the blue region (400-550 nm) due to the sulphur vacancy on the surface of the Fe3O4/ZnS nanocomposite. For a triply doped bifunctional nano-structure, the excitation spectra revealed broad absorption bands centered at around 270 nm, which were attributed to the 4f(7-7/2) -> 5d interconformational transition of the Ce3+ ion accompanied by narrow absorption lines arising from the 4f-4f intraconformational transitions of the Tb3+ ion. The emission spectra of the nanocomposites showed characteristic narrow emission lines assigned to the D(5-4) - F(7-6) transitions (J = 6-0) of the Tb3+ ion. The energy transfer process from the Ce3+ -> Gd3+ -> Tb3+ ions has also been presented and discussed. Furthermore, the structural, photoluminescence and magnetic properties of Fe3O4/ZnS@LaF3:RE3+ suggested that it may be an efficient candidate for magnetic light-converting molecular devices (MLMCDs) and high energy radiation detection.

**[P017-2017] “Comparison Between Conventional and Transferred DBD Plasma Jets for Processing of PDMS Surfaces”**

do Nascimento, F.; Machida, M.*; Canesqui, M. A.; Moshkalev, S. A.

This paper studies the processing of poly(dimethylsiloxane) (PDMS) surfaces using dielectric barrier discharge (DBD) plasma in two different assemblies, one using the primary plasma jet obtained from a conventional DBD and the other using a DBD plasma jet transfer. The evolution of water contact angle in the function of plasma processing time and in the function of aging time as well as the changes in the surface roughness of PDMS samples for both plasma treatments have been studied. The vibrational and rotational temperatures are compared for both plasmas and for the first time the vibrational temperature (Tvib) for the transferred plasma jet has been shown to be higher as compared with the primary jet. The increment in the Tvib value seems to be the main reason for the improvements in adhesion properties and surface wettability for the transferred plasma jet. Possible explanations for the increase in the vibrational temperature are presented.

**[P018-2017] “Comparison of activation energies for the electrical conductivity of silicate glasses obtained by dc and ac techniques”**

Ziemath, E. C.; Escanhoela, C. A.; Braunger, M. L.*

The electrical conductivity of glasses with composition (mol%) 22Na2O center dot 8CaO center dot 65SiO2 centered 0.71 and 0.81 eV were obtained. The differences between the values obtained by the dc and the ac methods are within experimental errors. The high electric field does not influence the concentration nor the mobility of the charge carriers in real populations and may explain why ring species are rare.
The dc method applied showed to be a suitable alternative to determine the temperature dependence of the electric conductivity of glasses to further calculation of the activation energy.

SOLID STATE IONICS 301, 146-151, 2017. DOI: 10.1016/j.ssi.2017.01.025

The UIO-66(2r)-(CO2H)(2) metal-organic framework has recently been revealed as a promising proton conducting material under humidification. Here, aMS-EVB3 molecular dynamics simulations are performed to reveal at the molecular level the structure, thermodynamics, and dynamics of the hydrated proton in three-dimensional (3D) cages MOF as a function of the water loading. It is found that the most stable proton solvation structure corresponds to a H7O3+ cation and that a transition between this complex and a Zundel cation likely governs the proton transport in this MOF occurring via a Grothuss-type mechanism. It is further shown that the formation of a H2O hydrogen-bonded bridge that connects the cages occurs only at high water concentration and this creates a path allowing the excess proton to jump from one cage to another. This leads to a faster self-diffusivity of proton at high water concentration, thereby supporting the increase of the proton conductivity with the water loading as experimentally evidenced.

[P020-2017] “Conduction electrons mediating the evolution from antiferromagnetic to ferromagnetic ordering in Gd(Co1-yFe)y(2)Zn20 (0 <= y <= 1)”

Cabrera-Baez, M.; Naranjo-Uribe, A.; Osorio-Guillen, J. M.; Rettori, C.*; Avila, M. A.

GdFeZn20 is a complex cage-like compound with an unusually high ferromagnetic ordering temperature (T-C = 86 K) for a very diluted Gd3+ magnetic sublattice, embedded in a matrix that features strong electron-electron correlations. Here, we report on a magnetic and electronic study of the substitutional intermetallic system Gd(Co1-yFe-y(2)Zn20 combining magnetization measurements plus first-principles density functional theory (DFT) calculations with temperature-dependent electron spin resonance (ESR). After accounting for electron-electron correlations and itinerant molecular field effects, the ESR results indicate that the exchange interaction between the Gd3+ is processed via a single band of d-type electrons at the Fermi level and the exchange interaction is covalent in nature [J(0)(fd) < 0] with a strong conduction electron (ce) momentum transfer dependence [J(fd)]. The DFT calculations support this scenario by indicating a major contribution of d-type ce at the Fermi level and a spin polarization in Y, Gd FeZn20 wherein the most stable configuration is antiferromagnetic between Gd3+ and ce spins. Our results demonstrate that the standard Ruderman-Kittel-Kasuya-Yosida mechanism cannot explain the ferromagnetic behavior of GdFeZn20 and a superexchangelike mechanism is proposed for this magnetic interaction. An “extended phase diagram” for the double substitution sequence YCoZn20. GdCoZn20. GdFeZn20 is presented and discussed.

[P021-2017] “Different approaches to analyze the dipolar interaction effects on diluted and concentrated granular superparamagnetic systems”

Controlled magnetic granular materials with different concentrations of magnetite nanoparticles immersed in a non-conducting polymer matrix were synthesized and, their macroscopic magnetic observables analyzed in order to advance towards a better understanding of the magnetic dipolar interactions and its effects on the obtained magnetic parameters. First, by means of X-ray diffraction, transmission electron microscopy, small angle X-ray scattering and X-ray absorption fine structure an accurate study of the structural properties was carried out. Then, the magnetic properties were analyzed by means of different models, including those that consider the magnetic interactions through long-range dipolar forces as: the Interacting Superparamagnetic Model (ISP) and the Vogel-Fulcher law (V-F). In systems with larger nanoparticle concentrations, magnetic results clearly indicate that the role played by the dipolar interactions affects the magnetic properties, giving rise to obtaining magnetic and structural parameters without physical meaning. Magnetic parameters as the effective anisotropic constant, magnetic moment relaxation time and mean blocking temperature, extracted from the application of the ISP model and V-F Law, were used to simulate the zero-field-cooling (ZFC) and field-cooling curves (FC). A comparative analysis of the simulated, fitted and experimental ZFC/FC curves suggests that the current models depict indeed our dilute granular systems. Notwithstanding, for concentrated samples, the ISP model infers that clustered nanoparticles are being interpreted as single entities of larger magnetic moment and volume, effect that is apparently related to a collective and complex magnetic moment dynamics within the cluster.

[P022-2017] “Effect of low electric fields on alpha scintillation light yield in liquid argon”

Agnes, P.; Albuquerque, I. F. M.; Segreto, E.*; et al.

Measurements were made of scintillation light yield of alpha particles from the Rn-222 decay chain within the Dark-Side-50 liquid argon time projection chamber. The light yield was found to increase as the applied electric field increased, with alphas in a 200 V/cm electric field exhibiting a similar to 2% increase in light yield compared to alphas in no field.

Gonzalez-Romero, R. L.*; Antonelli, A.*

We used a semi-empirical method to extract carrier relaxation times at different temperatures (tau(T)) in thermoelectric materials from a combination of experimental results and first-principles calculations. The methodology is based on the Boltzmann transport equation formalism within the relaxation time approximation. It can be applied to single crystals and polycrystalline materials. We applied the method to investigate the electronic transport properties of the clathrate compound BaGa16Ge30 type-I.
The calculations indicate that the carrier relaxation process in single crystals is dominated by electron-phonon scattering (tau proportional to T-3/2), while in polycrystalline materials scattering at grain boundaries dominates (tau similar to cte). The Seebeck coefficient, electrical conductivity, and electron heat conduction are in consistent agreement with experiment. Furthermore, the Slack relation for lattice heat conductivity was successfully applied to the material. The calculated figure of merit is in good agreement with experimental results.

[0024-2017] "Evidence for collectivity in pp collisions at the LHC"
Khachatryan, V.; Sirunyan, A. M.; Chatinellato, J. A.*; Tonelli Manganote, E. J.*; et al.
CMS Collaboration

Measurements of two- and multi-particle angular correlations in pp collisions at root s = 5, 7, and 13 TeV are presented as a function of charged-particle multiplicity. The data, corresponding to integrated luminosities of 1.0 pb(-1) (5 TeV), 6.2 pb(-1) (7 TeV), and 0.7 pb(-1) (13 TeV), were collected using the CMS detector at the LHC. The second-order (v(2)) and third-order (v(3)) azimuthal anisotropy harmonics of unidentified charged particles, as well as v(2) of K-S(0) and Lambda/(Lambda bar) over bar, bar, bar, bar, bar, bar particles, are extracted from long-range two-particle correlations as functions of particle multiplicity and transverse momentum. For high-multiplicity pp events, a mass ordering is observed for the v(2) values of charged hadrons (mostly pions), K-S(0), and Lambda/(Lambda bar) over bar, Lambda/(Lambda bar) over bar, bar, bar, bar, bar, bar over bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, bar, Santos, F. G. S.; Espinell, Y. A. V.; Luiz, G. O.; Benevides, R. S.; Wiederhecker, G. S.; Alegre, T. P. M.*

Optomechanical cavities have proven to be an exceptional tool to explore fundamental and applied aspects of the interaction between mechanical and optical waves. Here we demonstrate a novel optomechanical cavity based on a disk with a radial mechanical bandgap. This design confines light and mechanical waves through distinct physical mechanisms which allows for independent control of the mechanical and optical properties. Simulations foresee an optomechanical coupling rate \( g_0 \) reaching 2 \( \text{pi} \times 100 \) kHz for mechanical frequencies around 5 GHz as well as anchor loss suppression of 60 dB. Our device design is not limited by unique material properties and could be easily adapted to allow for large optomechanical coupling and high mechanical quality factors with other promising materials. Finally, our devices were fabricated in a commercial silicon photonics facility, demonstrating \( g(0)/2 \text{pi} \approx 23 \) kHz for mechanical modes with frequencies around 2 GHz and mechanical Q-factors as high as 2300 at room temperature, also showing that our approach can be easily scalable and useful as a new platform for multimode optomechanics.

**[P029-2017] “Impact of atmospheric effects on the energy reconstruction of air showers observed by the surface detectors of the Pierre Auger Observatory”**

Pierre Auger Collaboration

Atmospheric conditions, such as the pressure (\( P \)), temperature (\( T \)) or air density (\( \rho \) proportional to \( P/T \)), affect the development of extended air showers initiated by energetic cosmic rays. We study the impact of the atmospheric variations on the reconstruction of air showers with data from the arrays of surface detectors of the Pierre Auger Observatory, considering separately the one with detector spacings of 1500m and the one with 750m spacing. We observe modulations in the event rates that are due to the influence of the air density and pressure variations on the measured signals, from which the energy estimators are obtained. We show how the energy assignment can be corrected to account for such atmospheric effects.

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A. *; Tonelli Manganote, E. J. *; et al.

CMS Collaboration

An inclusive search for supersymmetry using razor variables is performed in events with four or more jets and no more than one lepton. The results are based on a sample of proton-proton collisions corresponding to an integrated luminosity of 2.3 fb\(^{-1}\) collected with the CMS experiment at a center-of-mass energy of \( \sqrt{s} = 13 \) TeV. No significant excess over the background prediction is observed in data, and 95% confidence level exclusion limits are placed on the masses of new heavy particles in a variety of simplified models. Assuming that pair-produced gluinos decay only via three-body processes involving third-generation quarks plus a neutralino, and that the neutralino is the lightest supersymmetric particle with a mass of 200 GeV, gluino masses below 1.6 TeV are excluded for any branching fractions for the individual gluino decay modes.

For some specific decay mode scenarios, gluino masses up to 1.65 TeV are excluded. For decays to first- and second-generation quarks and a neutralino with a mass of 200 GeV, gluinos with masses up to 1.4 TeV are excluded. Pair production of top squarks decaying to a top quark and a neutralino with a mass of 100 GeV is excluded for top squark masses up to 750 GeV.

**[P031-2017] “J/Psi suppression at forward rapidity in Pb-Pb collisions at root sNN=5.02 TeV”**

ALICE Collaboration

The inclusive J/Psi production has been studied in Pb-Pb and pp collisions at the centre-of-mass energy per nucleon pair root \( s_{NN} = 5.02 \) TeV, using the ALICE detector at the CERN LHC. The J/Psi meson is reconstructed, in the centre-of-mass rapidity interval 2.5 < \( y < 4 \) and in the transverse- momentum range \( p(T) < 12 \) GeV/c, via its decay to a muon pair. In this Letter, we present results on the inclusive J/Psi cross section in pp collisions at root \( s = 5.02 \) TeV and on the nuclear modification factor R-AA. The latter is presented as a function of the centrality of the collision and, for central collisions, as a function of the transverse momentum \( p(T) \) of the J/Psi. The measured R-AA values indicate a suppression of the J/Psi in nuclear collisions and are then compared to our previous results obtained in Pb-Pb collisions at root \( s_{NN} = 2.76 \) TeV. The ratio of the R-AA values at the two energies is also computed and compared to calculations of statistical and dynamical models. The numerical value of the ratio for central events (0-10% centrality) is 1.17 ± 0.04\( ( \text{stat}) \)/0.20\( ( \text{syst}) \). In central events, as a function of \( p(T) \), a slight increase of R-AA with collision energy is visible in the region \( 2 < p(T) < 6 \) GeV/c. Theoretical calculations qualitatively describe the measurements, within uncertainties.

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A. *; Tonelli Manganote, E. J. *; et al.

CMS Collaboration

Improved jet energy scale corrections, based on a data sample corresponding to an integrated luminosity of 19.7 fb\(^{-1}\) collected by the CMS experiment in proton-proton collisions at a center-of-mass energy of 8 TeV, are presented. The corrections as a function of pseudorapidity \( \eta \) and transverse momentum \( p(T) \) are extracted from data and simulated events combining several channels and methods. They account successively for the effects of pileup, uniformity of the detector response, and residual data-simulation jet energy scale differences and are then compared to our previous results obtained in Pb-Pb collisions at root \( s_{NN} = 2.76 \) TeV. The inclusive J/Psi production has been studied in Pb-Pb and pp collisions at the centre-of-mass energy per nucleon pair root \( s_{NN} = 5.02 \) TeV, using the ALICE detector at the CERN LHC. The J/Psi meson is reconstructed, in the centre-of-mass rapidity interval 2.5 < \( y < 4 \) and in the transverse- momentum range \( p(T) < 12 \) GeV/c, via its decay to a muon pair. In this Letter, we present results on the inclusive J/Psi cross section in pp collisions at root \( s = 5.02 \) TeV and on the nuclear modification factor R-AA. [P033-2017] "Magnetic and magnetocaloric properties of DyMn2Si2 compound with multiple magnetic phase transition"

dos Reis, D. C.; Franca, E. L. T.; de Paula, V. G.*; dos Santos, A. O.; Coelho, A. A.;* Cardoso, L. P.;* da Silva, L. M.

Structural, magnetic and magnetocaloric properties of the ternary intermetallic compound DyMn2Si2 are studied by X-ray diffraction and magnetization measurements. It is found that DyMn2Si2 crystalizes with tetragonal ThCr2Si2-type structure and exhibits four successive magnetic transitions at low temperature, around 20 K, 31 K, 82 K and 82 K, named respectively as T-1, T-2, T-3 and T-4 transitions. Large values of magnetic field (35 kOe) favor antiferromagnetic clusters and give rise to exchange bias effect. The different responses of T-2 and T-3 to field change, includes two non-identical isothermal entropy change (-Delta S-M) peaks. The maximum values of -Delta S-M occur in temperatures around T-3 and reaches 8.2 J/kgK, for a magnetic field change of 50 kOe. Also, the presence of transitions T-2 and T-3 close to each other induces a table-like magnetocaloric effect (MCE) in a wide temperature range. Thus, the peculiar magnetic properties observed for DyMn2Si2 compound are interesting for low temperature magnetic refrigeration.

JOURNAL OF MAGNETISM AND MAGNETIC MATERIALS 424, 84-88, 2017. DOI: 10.1016/j.jmmm.2016.10.019

Granja, L. P.; Martinez, E. D.*; Troiani, H.; Sanchez, C.; Illia, G. J. A. A.

In the past decade, the surprising, magnetic behavior of gold nanoparticles has been reported. This unexpected-property is mainly attributed both to size and surface effects. Mesoporous thin films are ideal matrices for metallic nanoparticles inclusion, because of their highly accessible and tailorable pore systems that lead to completely tunable chemical environments. Exploiting these features, we synthesized Au nanoparticles within mesoporous titania thin films (film thickness of similar to 0.15 nm and pore diameter of similar to 5nm), and we studied their magnetic properties under confinement. Here, we present the results of the magnetization as a function of temperature and magnetic field for this system, which are consistent with the previously reported for free (unconfined) thiol-capped gold nanoparticles. The successful inclusion of stable magnetic Au nanoparticles within thin transparent mesoporous thin films opens the gates for the application of these nanocomposites in two-dimensional (2D) microdevices technology and magneto-optical devices.

[P035-2017] "Maxwell times in higher-order generalized hydrodynamics: Classical fluids, and carriers and phonons in semiconductors"

Rodrigues, C. G.; Silva, C. A. B.; Ramos, J. G.;* Luzzi, R.*

A family of what can be so-called Maxwell times which arises in the context of higher-order generalized hydrodynamics (HOGH; also called mesoscopic hydrothermodynamics) is evidenced. This is done in the framework of a HOGH built within a statistical formalism in terms of a nonequilibrium statistical ensemble formalism. It consists in a description in terms of the densities of particles and energy and their fluxes of all orders, with the motion described by a set of coupled non-linear integro-differential equations involving them. These Maxwell times have a fundamental role in determining the type of hydrodynamic motion that the system would display in the given conditions and constraints. They determine a Maxwell viscous force not present in the usual hydrodynamic equations, for example, in Navier-Stokes equation.

[P036-2017] "Measurement of the transverse momentum spectra of weak vector bosons produced in proton-proton collisions at root s=8TeV"

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.;* Tonelli Manganote, E. J.;* et al.

CMS Collaboration

The transverse momentum spectra of weak vector bosons are measured in the CMS experiment at the LHC. The measurement uses a sample of proton-proton collisions at root s = 8TeV, collected during a special low-luminosity running that corresponds to an integrated luminosity of 18: 4 +/- 0: 5 pb(-1). The production of W bosons is studied in both electron and muon decay modes, while the production of Z bosons is studied using only the dimuon decay channel. The ratios of W+ to W+ and Z to W+ di ff ential cross sections and ratios are compared with theoretical predictions up to next-to-next leading order in QCD.

[P037-2017] "Measurements of differential cross sections for associated production of a W boson and jets in proton-proton collisions at root s=8TeV"

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.;* Tonelli Manganote, E. J.;* et al.

CMS Collaboration

Differential cross sections for a W boson produced in association with jets are measured in a data sample of proton-proton collisions at a center-of-mass energy of 8 TeV recorded with the CMS detector and corresponding to an integrated luminosity of 19.6 fb(-1). The W bosons are identified through their decay mode W+->mu nu. The cross sections are reported as functions of H-T for different jet multiplicities. Distributions of the angular correlations between the jets and the muon are examined, as well as the average number of jets as a function of H-T and as a function of angular variables. The measured di ff ential cross sections and ratios are compared with theoretical predictions up to next-to-next leading order in QCD.

[P038-2017] “Measurements of the t(t)over-bar production cross section in lepton plus jets final states in pp collisions at 8 and ratio of 8 to 7 cross sections”

Khachatryan, V. · Sirunyan, A. M. · Chinellato, J. A.* · Tonelli Manganote, E. J.* · et al.

CMS Collaboration

A measurement of the top quark pair production cross section in proton-proton collisions at the centre-of-mass energy of 8 TeV is presented using data collected with the CMS detector at the LHC, corresponding to an integrated luminosity of 19.6. This analysis is performed in the decay channels with one isolated, high transverse momentum electron or muon and at least four jets, at least one of which is required to be identified as originating from hadronization of a b quark. The calibration of the jet energy scale and the efficiency of b jet identification are determined from data. The measured cross section is . This measurement is compared with an analysis of 7 data, corresponding to an integrated luminosity of 5.0, to determine the ratio of 8 to 7 cross sections, which is found to be . The measurements are in agreement with QCD predictions up to next-to-next-to-leading order.

[P039-2017] “Measuring the leptonic CP phase in neutrino oscillations with nonunitary mixing”

Ge, S. F. · Pasquini, P.* · Tortola, M. · Valle, J. W. F.

Non-unitary neutrino mixing implies an extra CP violating phase that can fake the leptonic Dirac CP phase delta(CP) of the simplest three-neutrino mixing benchmark scheme. This would hinder the possibility of probing for CP violation in accelerator-type experiments. We take T2K and T2HK as examples to demonstrate the degeneracy between the “standard” (or “unitary”) and “nonunitary” CP phases. We find, under the assumption of nonunitary mixing, that their CP sensitivities severely deteriorate. Fortunately, the TNT2K proposal of supplementing T2(H)K with a mu DAR source for better measurement of delta(CP) can partially break the CP degeneracy by probing both cos delta(CP) and sin delta(CP) dependences in the wide spectrum of the mu DAR flux. We also show that the further addition of a near detector to the mu DAR setup can eliminate the degeneracy completely.

We show that highly ordered two-dimensional (2D) chessboard arrays consisting of a periodic arrangement of two different molecules can be obtained by self-assembly of unsubstituted metal-phthalocyanines (metal-Pcs) on a suitable substrate serving as the template. Specifically, CuPc + MnPc and CuPc + CoPc mixtures sort into highly ordered Cu/ Mn and Cu/Co chessboard arrays on the square p(10 x 10) reconstruction of bismuth on Cu(100). Such created birillolecular chessboard assemblies emerge from the site-specific interactions between the central transition-metal ions and the periodically reconstructed substrate. This work provides a conceptually new approach to induce 2D chessboard patterns in that no functionalization of the molecules is needed.

Thousands of people die every year from burn injuries. The aim of this study is to evaluate the feasibility of high intensity femtosecond lasers as an auxiliary treatment of skin burns. We used an in vivo animal model and monitored the healing process using different imaging modalities: histology, Optical Coherence Tomography (OCT), Second Harmonic Generation (SHG), and Fourier Transform Infrared (FTIR) spectroscopy. 3 dorsal areas of 20 anesthetized Wistar rats were burned by water vapor exposure and subsequently treated either by classical surgical debridement, by laser ablation, or left without treatment. Skin burn tissues were non-invasively characterized by OCT images and biopsied for further histopathology analysis, SHG imaging and FTIR spectroscopy at 3, 5, 7 and 14 days after burn. The laser protocol was found as efficient as the classical treatment for promoting the healing process. The study concludes to the validation of femtosecond ultra-short pulses laser treatment for skinburns, with the advantage of minimizing operatory trauma.

Oliveira, R.; Marques, T. H. R.*; Bilro, L.; Nogueira, R.; Cordeiro, C. M. B.*

We report the fabrication of a multimode interferometer (MMI), based on a multimode polymer optical fiber (POF), sandwiched between two single-mode silica fibers. The POF used in this work is a step-index fiber with core and cladding composed of a cycloolefin polymer (COP) and PMMA, respectively. The low moisture absorption of the COP material and the benefit of having an exposed core for refractive indexmeasurements in MMI devices lead us to perform an etching of the PMMAlayer. Additionally, we report the inscription of a Bragg grating in the COP core material of an etched single-mode-multimode-single-mode (SMS) structure. The two fiber structures were simultaneously characterized to strain, temperature, humidity, and refractive index. The ability to detect refractive index by using a POF-based SMS structure is reported for the first time in this paper. Additionally, the capability for dual parameter measurement was discussed using both FBG and SMS structures.

[P043-2017] “Non-thermal atmospheric pressure plasma jet applied to inactivation of different microorganisms”

Nishime, T. M. C.; Borges, A. C.; Koga-Ito, C. Y.; Machida, M.*; Hein, L. R. O.; Kostov, K. G.

Non-thermal atmospheric pressure plasma jets (APJPs) are capable of generating cold plasma plumes that are not confined by electrodes, which makes them very attractive for biomedical applications. In the present work, the inactivation efficiency of cold APPJ was evaluated against three pathogenic microorganisms with different cell wall characteristics.
The Gram-positive bacterium Enterococcus faecalis (ATCC 29212), the Gram-negative bacterium Pseudomonas aeruginosa (ATCC 15442) and the fungus Candida albicans (SC 5314) were plated on standard Petri dishes filled with specific culture media. The plasma jet with mean power of 1.8 W was directed perpendicularly on agar plates and the system was flushed with pure helium at two different flows, 2.0 and 4.0 SLM. During the treatments, time and distance between nozzle and agar were varied. The presence of excited reactive species was confirmed by optical emission spectroscopy. Scanning electron microscopy (SEM) was applied for investigation of cell morphology. The microbical efficiency was evaluated by measuring the area of inhibition zone (where there was no cell growth). For different flows of helium, no significant difference of inhibition zone size was noted for the same microbial species. However, high flows led to formation of non-homogenous inhibition zones, presenting microcolonies distributed through the inactivated region. The Gram-positive bacterium was more susceptible to the plasma antimicrobial effects than the other microorganisms.

[PO44-2017] “Observation of Charge-Dependent Azimuthal Correlations in p-Pb Collisions and Its Implication for the Search for the Chiral Magnetic Effect”

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Manganote, E. J.*; et al.
CMS Collaboration

Charge-dependent azimuthal particle correlations with respect to the second-order event plane in p-Pb and PbPb collisions at a nucleon-nucleon center-of-mass energy of 5.02 TeV have been studied with the CMS experiment at the LHC. The measurement is performed with a three-particle correlation technique, using two particles with the same or opposite charge within the pseudorapidity range 4.4 < |η| < 5. The observed differences between the same and opposite sign correlations, as functions of multiplicity and, gap between the two charged particles, are of similar magnitude in p-Pb and PbPb collisions at the same multiplicities. These results pose a challenge for the interpretation of charge-dependent azimuthal correlations in heavy ion collisions in terms of the chiral magnetic effect.

[PO46-2017] “One-step electrodeposited 3D-ternary composite of zirconia nanoparticles, rGO and polypyrrole with enhanced supercapacitor performance”

Supercapacitor electrodes consisting of conjugated polymers (CP), metal oxides and graphene nanosheets have been explored as a strategy to achieve high specific capacitance, power, energy density, and stability. In this work, we synthesized a 3D structure composed of zirconia oxide nanoparticles (ZrO2), reduced graphene oxide (rGO) and polypyrrole (PPy), using a simple and easily scalable one-step chronopotentiometry method. Detailed characterization revealed that the addition of rGO and ZrO2 modified the morphology of the electrode material. The capacitance of the resulting architecture improved by up to a 100%. The ternary composite featured high stability, with an increase of 5% in capacitance after a thousand cycles. DFT and MD simulations were carried out in order to provide further insight on the role of zirconia.

[PO47-2017] “Partial Quenching of the Magnetic Moments in Polycrystalline CoAl (x) Co1-x (2)O-4 Samples (0 < x < 0.35)”

Oliveira, M. P.; Silva, L. S.; Mercena, S. G.; Coelho, A. A.*; Meneses, C. T.; Duque, J. G. S.*

In this work, the effect of Al3+ doping in polycrystalline CoAl (x) Co1-x (2)O-4 samples (x < 0.35) was studied. Samples have been synthesized via conventional state solid method. X-ray diffraction (XRD) measurements carried out at room temperature reveal that a single cubic phase has been successfully obtained for all samples. Magnetization measurements as function of temperature (2 < T < 300 K) were collected in a commercial DC superconducting quantum interference device magnetometer. The observation of an antiferromagnetic transition for all samples confirms that Co3+ ions located on octahedral sites are low spin (S = 0). On the other hand, the transition temperatures are unaffected by the Co3+-doping indicating that the empty e (g) orbitals do not play an important role in the antiferromagnetic interaction between Co2+ sited on tetrahedral sites. Besides, the evaluation of effective magnetic moment from T-dependence of magnetic susceptibility reveals that the effective moment is not totally quenched. This fact confirms both of the crystal field effects experimented by the Co ions is site-dependent and it is stronger for Co ions located in octahedral sites than tetrahedral ones.

Recently, there has been an explosive growth in research based on hybrid lead halide perovskites for photovoltaics owing to rapid improvements in efficiency. The advent of these “materials for solar applications has led to widespread interest in understanding the key enabling properties of these materials.
This has resulted in renewed interest in related compounds and a search for materials that may replicate the defect-tolerant properties and long lifetimes of the hybrid lead-halide perovskites. Given the rapid pace of development of the field, the rises in efficiencies of these systems have outpaced the more basic understanding of these materials. Measuring or calculating the basic properties, such as crystal/electronic structure and composition, can be challenging because some of these materials have anisotropic structures, and/or are composed of both heavy metal cations and volatile, mobile, light elements. Some consequences are beam damage during characterization, composition change under vacuum, or compound effects, such as the alteration of the electronic structure through the influence of the substrate. These effects make it challenging to understand the basic properties integral to optoelectronic operation. Compounding these difficulties is the rapid pace with which the field progresses. This has created an ongoing need to continually evaluate best practices with respect to characterization and calculations, as well as to identify inconsistencies in reported values to determine if those inconsistencies are rooted in characterization methodology or materials synthesis. This article describes the difficulties in characterizing hybrid lead halide perovskites and new materials and how these challenges may be overcome. The topic was discussed at a seminar at the 2015 Materials Research Society Fall Meeting & Exhibit. This article highlights the lessons learned from the seminar and the insights of some of the attendees, with reference to both recent literature and controlled experiments to illustrate the challenges discussed. The focus in this article is on crystallography, composition measurements, photoemission spectroscopy, and calculations on perovskites and new, related absorbers. We suggest how the reporting of the important artifacts could be streamlined between groups to ensure reproducibility as the field progresses.

**[P049-2017] “Schwinger mechanism in linear covariant gauges”**

Aguilar, A. C.*; Binosi, D.; Papavassiliou, J.

In this work we explore the applicability of a special gluon mass generating mechanism in the context of the linear covariant gauges. In particular, the implementation of the Schwinger mechanism in pure Yang-Mills theories hinges crucially on the inclusion of massless bound-state excitations in the fundamental nonperturbative vertices of the theory. The dynamical formation of such excitations is controlled by a homogeneous linear Bethe-Salpeter equation, whose nontrivial solutions have been studied only in the Landau gauge. Here, the form of this integral equation is derived for general values of the gauge-fixing parameter, under a number of simplifying assumptions that reduce the degree of technical complexity. The kernel of this equation consists of fully dressed gluon propagators, for which recent lattice data are used as input, and of three-gluon vertices dressed by a single form factor, which is modeled by means of certain physically motivated Ansätze. The gauge-dependent terms contributing to this kernel impose considerable restrictions on the infrared undetermined vertex form factor; specifically, only infrared finite Ansätze are compatible with the existence of nontrivial solutions. When such Ansätze are employed, the numerical study of the integral equation reveals a continuity in the type of solutions as one varies the gauge-fixing parameter, indicating a smooth departure from the Landau gauge. Instead, the logarithmically divergent form factor displaying the characteristic “zero crossing,” while perfectly consistent in the Landau gauge, has to undergo a dramatic qualitative transformation away from it, in order to yield acceptable solutions. The possible implications of these results are briefly discussed.

**[P050-2017] “Search for anomalous Wtb couplings and flavour-changing neutral currents in t-channel single top quark production in pp collisions at root s=7 and 8 TeV”**

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Manganote, E. J.*; et al. CMS Collaboration

Single top quark events produced in the t channel are used to set limits on anomalous Wtb couplings and to search for top quark flavour-changing neutral current (FCNC) interactions. The data taken with the CMS detector at the LHC in proton-proton collisions at and 8 TeV correspond to integrated luminosities of 5.0 and 19.7 fb(-1), respectively. The analysis is performed using events with one muon and two or three jets. A Bayesian neural network technique is used to discriminate between the signal and backgrounds, which are observed to be consistent with the standard model prediction. The 95% confidence level (CL) exclusion limits on anomalous right-handed vector, and left- and right-handed tensor Wtb couplings are measured to be vertical bar f (V) (R) vertical bar < 0.16,aEuro vertical bar f (T) (L) vertical bar < 0.057, and -0.049 < f (T) (R) vertical bar < 0.048, respectively. For the FCNC couplings kappa (tug) and kappa (tcg), the 95% CL upper limits on coupling strengths are vertical bar kappa (tug)vertical bar/vertical bar Lambda < 4.1 x 10(- 3) TeV-1 and vertical bar kappa (tcg)vertical bar/vertical bar Lambda < 1.8 x 10( - 2) TeV-1, where I > is the scale for new physics, and correspond to upper limits on the branching fractions of 2.0 x 10( - 5) and 4.1 x 10( - 4) for the decays t -> ug and t -> cg, respectively.

**[P051-2017] “Search for CP violation in t(\over-bar)over-bar production and decay in proton-proton collisions at root s=8 TeV”**

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Manganote, E. J.*; et al. CMS Collaboration

The results of a first search for CP violation in the production and decay of top quark-antiquark (t (t) over bar) pairs are presented. The search is based on asymmetries in T-odd, triple-product correlation observables, where T is the time-reversal operator. The analysis uses a sample of proton-proton collisions at root s = 8 TeV collected by the CMS experiment, corresponding to an integrated luminosity of 19.7 fb(-1). Events are selected having one electron or muon and at least four jets. The T-odd observables are measured using four-momentum vectors and left- and right-handed tensor Wtb couplings are measured with a Compressed Mass Spectrum in the Vector Boson Fusion topology. The results are compared to the standard model prediction, and left- and right-handed tensor Wtb couplings are measured with a Compressed Mass Spectrum in the Vector Boson Fusion topology.

**JOURNAL OF HIGH ENERGY PHYSICS [3], 101, 2017. DOI: 10.1007/JHEP03(2017)101**

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Manganote, E. J.*; et al. CMS Collaboration

A first search for pair production of dark matter candidates through vector boson fusion in proton-proton collisions at root s = 8 TeV is performed with the CMS detector. The vector boson fusion topology enhances missing transverse momentum, providing a way to probe supersymmetry, even in the case of a compressed mass spectrum. The data sample corresponds to an integrated luminosity of 18.5 fb(-1), recorded by the CMS experiment. The observed dijet mass spectrum is consistent with the standard model expectation.
In an effective field theory, dark matter masses are explored as a function of contact interaction strength. The most stringent limit on bottom squark production with mass below 315 GeV is also reported, assuming a 5 GeV mass difference with respect to the lightest neutralino.

**[P053-2017]** "Search for dark matter and unparticles in events with a Z boson and missing transverse momentum in proton-proton collisions at root s=13 TeV"

Sirunyan, A. M.; Tumasyan, A.; Chinellato, J. A.*; Tonelli Mangano, E. J.*; et al.

CMS Collaboration

A search for dark matter and unparticle production at the LHC has been performed using events containing two charged leptons (electrons or muons), consistent with the decay of a Z boson, and large missing transverse momentum. This study is based on data collected with the CMS detector in 2015, corresponding to an integrated luminosity of 2.3 fb(-1) of proton-proton collisions at the LHC, at a center-of-mass energy of 13 TeV. No excess over the standard model expectation is observed. Compared to previous searches in this topology, which exclusively relied on effective field theories, the results are interpreted in terms of a simplified model of dark matter production for both vector and axial vector couplings between a mediator and dark matter particles. The first study of this class of models using CMS data at root s = 13 TeV is presented. Additionally, effective field theories of dark matter and unparticle production are used to interpret the data.

**[P055-2017]** "Search for heavy neutrinos or third-generation leptoquarks in final states with two hadronically decaying tau leptons and two jets in proton-proton collisions at root s=13 TeV"

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Mangano, E. J.*; et al.

CMS Collaboration

A search for new particles has been conducted using events with two high transverse momentum (pT) T leptons that decay hadronically, at least two high-pT jets, and missing transverse energy from the T lepton decays. The analysis is performed using data from proton-proton collisions, collected by the CMS experiment in 2015 at root s = 13 TeV, corresponding to an integrated luminosity of 2.1 fb(-1). The results are interpreted in two physics models. The first model involves heavy right-handed neutrinos, N-l (l = e, mu, tau), and right-handed charged bosons, WR, arising in a left-right symmetric extension of the standard model. Masses of the W-R boson below 2.35 (1.63) TeV are excluded at 95% confidence level, assuming the N-tau mass is 0.8 (0.2) times the mass of the W-R boson and that only the NT flavor contributes to the WR decay width. In the second model, pair production of third-generation scalar leptoquarks that decay into (TT)bb is considered. Third-generation scalar leptoquarks with masses below 740 GeV are excluded, assuming a 100% branching fraction for the leptoquark decay to a T lepton and a bottom quark. This is the first search at hadron colliders for the third-generation Majorana neutrino, as well as the first search for third-generation leptoquarks in the final state with a pair of hadronically decaying T leptons and jets.

**Journal of High Energy Physics** 3[1], 077, 2017. DOI: 10.1007/JHEP03(2017)077

**[P056-2017]** "Search for heavy resonances decaying to tau lepton pairs in proton-proton collisions at root s=13 TeV"

Rui Vargas, J. C.; Battilana, C.; Chinellato, J. A.*; et al.

A search for heavy resonances that decay to tau lepton pairs is performed using proton-proton collisions at root s = 13 TeV. The data were collected with the CMS detector at the CERN LHC and correspond to an integrated luminosity of 2.2 fb(-1). The observations are in agreement with standard model predictions. An upper limit at 95% confidence level on the product of the production cross section and branching fraction into tau lepton pairs is calculated as a function of the resonance mass. For the sequential standard model, the presence of Z' bosons decaying into tau lepton pairs is excluded for Z' masses below 2.1 TeV, extending previous limits for this final state. For the topcolor-assisted technicolor model, which predicts Z' bosons that preferentially couple to third-generation fermions, Z' masses below 1.7 TeV are excluded, representing the most stringent limit to date.

**[P057-2017]** "Search for high-mass diphoton resonances in proton-proton collisions at 13 TeV and combination with 8 TeV search"

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J.*; Tonelli Mangano, E. J.*; et al.

CMS Collaboration

A search for the resonant production of high-mass photon pairs is presented. The search focuses on spin-0 and spin-2 resonances with masses between 0.5 and 4.5 TeV, and with widths, relative to the mass, between 1.4 x 10(-4) and 5.6 x 10(-2). The data sample corresponds to an integrated luminosity of 12.9 fb(-1) of proton-proton collisions collected with the CMS detector in 2016 at a center-of-mass energy of 13 TeV. No significant excess is observed relative to the standard model expectation. The results of the search are combined statistically with those previously obtained in 2012 and 2015 at root s = 8 and 13 TeV, respectively, corresponding to integrated luminosities of 19.7 and 3.3 fb(-1), to derive exclusion limits on scalar resonances produced through gluon-gluon fusion, and on Randall-Sundrum gravitons. The lower mass limits for Randall-Sundrum gravitons range from 1.95 to 4.45 TeV for coupling parameters between 0.01 and 0.2. These are the most stringent limits on Randall-Sundrum graviton production to date.
[P058-2017] “Search for high-mass $Z$ gamma resonances in $e(\mu)e(-\mu)\gamma\gamma$ and $\mu(\mu)\mu(-\mu)\gamma\gamma$ final states in proton–proton collisions at root $s=8$ and 13 TeV”

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Manganote, E. J.*; et al.

CMS Collaboration

This paper describes the search for a high-mass narrow-width scalar particle decaying into a $Z$ boson and a photon. The analysis is performed using proton-proton collision data recorded with the CMS detector at the LHC at center-of-mass energies of 8 and 13 TeV, corresponding to integrated luminosities of 19.7 and 2.7 fb$^{-1}$, respectively. The $Z$ bosons are reconstructed from opposite-sign electron or muon pairs. No statistically significant signal is observed. The 95% confidence level upper limit on the scalar particle production cross section and the branching fraction of the $Z$ decaying into electrons or muons, which range from 280 to 20 fb for resonance masses between 200 and 2000 GeV.

[061-2017] “Searches for invisible decays of the Higgs boson in pp collisions at root $s=7$, 8, and 13 TeV”

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Manganote, E. J.*; et al.

CMS Collaboration

Searches for invisible decays of the Higgs boson are presented. The data collected with the CMS detector at the LHC correspond to integrated luminosities of 5.1, 19.7, and 2.3 fb$^{-1}$ at center-of-mass energies of 7, 8, and 13 TeV, respectively. The search channels target Higgs boson production via gluon fusion, vector boson fusion, and in association with a vector boson. Upper limits are placed on the branching fraction of the Higgs boson decay to invisible particles, as a function of the assumed production cross sections. The combination of all channels, assuming standard model production, yields an observed (expected) upper limit on the invisible branching fraction of 0.24 (0.23) at the 95% confidence level. The results are also interpreted in the context of Higgs-portal dark matter models.

[062-2017] “Simplified fabrication of integrated microfluidic devices using fused deposition modeling 3D printing”

Gaal, G.*; Mendes, M.*; de Almeida, T. P.; Piazzetta, M. H. O.; Gobbi, A. L.; Riu, A.*; Rodrigues, V.*

Microfluidic devices based on polydimethylsiloxane shown a plethora of experimental possibilities due to good transparency, flexibility and ability to adhere reversibly and irreversibly to distinct materials. Though PDMS is a milestone in microfluidic developments, its cost and handling directed the field to search for new options. 3D printing technology nowadays starts a revolution offering materials and possibilities that can contribute positively to current methodologies. Here we explored the fused deposition modeling 3D printing technique to obtain integrated, transparent and sealed microchannels made with polyactic acid, a cheap alternative material to set up microfluidic systems. Using a home-made 3D printer, devices could be assembled in a simplified process, enabling the integration of different materials such as paper, glass, wire and polymers within the microchannel.
To demonstrate the efficacy of this approach, a 3D-printed electronic tongue sensor was built, enabling the distinction of basic tastes below the human threshold.

[**P063-2017**] “Size Control of Silver-Core/Silica-Nanoparticles Fabricated by Laser-Ablation-Assisted Chemical Reduction”

Ermakov, V. A.*, Jimenez-Villar, E.; Clemente da Silva Filho, J. M.*; Yassitepe, E.; Mogill, N. V. V.; Ikawa, F.*; Sa, G. F.; Cesar, C. L.*; Marquest, F. C.*

Aqueous colloidal silver nanoparticles have substantial potential in biological application as markers and antibacterial agents and in surface-enhanced Raman spectroscopy applications. A simple method of fabrication and encapsulation into an inert shell is of great importance today to make their use ubiquitous. Here we show that colloids of silver-core/silica-shell nanoparticles can be easily fabricated by a laser-ablation-assisted chemical reduction method and their sizes can be tuned in the range of 2.5 to 6.3 nm by simply choosing a proper water ethanol proportion. The produced silver nanoparticles possess a porous amorphous silica shell that increases the inertness and stability of colloids, which decreases their toxicity compared with those without silica. The presence of a thin 2 to 3 nm silica shell was proved by EDX mapping. The small sizes of nanoparticles achieved by this method were analyzed using optical techniques, and they show typical photoluminescence in the UV-vis range that shifts toward higher energies with decreasing size.

[**P064-2017**] “Speciation in the Derrida-Higgs model with finite genomes and spatial populations”

de Aguiar, M. A. M.*

The speciation model proposed by Derrida and Higgs demonstrated that a sexually reproducing population can split into different species in the absence of natural selection or any type of geographic isolation, provided that mating is assortative and the number of genes involves in the process is infinite. Here we revisit this model and simulate it for finite genomes, focusing on the question of how many genes it actually takes to trigger neutral sympatric speciation. We find that, for typical parameters used in the original model, it takes the order of 105 genes. We compare the results with a similar spatially explicit model where about 100 genes suffice for speciation. We show that when the number of genes is small the species that emerge are strongly segregated in space. For a larger number of genes, on the other hand, the spatial structure of the population is less important and the species distribution overlap considerably.

[**P065-2017**] “Surface analysis and shear bond strength of zirconia on resin cements after non-thermal plasma treatment and/or primer application for metallic alloys”

Vechiato, A. J.; Matos, A. O.; Landers, R.*; Goiato, M. C.; Rangel, E. C.; De Souza, G. M.; Barao, V. A. R.; dos Santos, D. M.

There is no established protocol for bonding zirconia (Y-TZP) with resin cements. Non-thermal plasma (NTP) may be an alternative for the clinical problems related to adhesion.

The purpose of the present study was to characterize the surface of Y-TZP exposed to methane (CH4) NTP or coated with a layer of primer for metal alloys and the association between the two methods and to evaluate the effect of NTP treatment on bond strength between Y-TZP and two resin cements. A total of 235 Y-TZP discs (8 x 2 mm) were distributed into five groups: Co (no surface treatment), Pr (primer), NTP (methane plasma), Pr + NTP and NTP + Pr. The effect of the treatment type on the surface free energy, morphology, topography and chemical composition of the Y-TZP discs was investigated. The discs were cemented to composite resin substrates using Panavia F2.0 or RelyX U200. Shear bond strength (n = 10) analyses were performed (1 mm/min) before and after thermocycling (5-55 degrees C, 2000 cycles) on the bonded specimens. The data were analyzed with one and three-way ANOVAs and Bonferroni tests (alpha = 0.05). NTP reduced the surface energy and roughness of the Y-TZP discs. SEM-EDS and XPS analyses showed the presence of the organic thin film, which significantly improved the bond strength results when Rely X U200 was used, whereas the primer treatment was more effective with Panavia F2.0. Thermocycling significantly reduced the bond strength results of the NIP and Pr + NTP groups cemented with Rely X U200 and the Pr and NTP + Pr groups cemented with Panavia F2.0. Nonthermal plasma improves the bond strength between Rely X U200 and Y-TZP and also seems to have water-resistant behavior, whereas Panavia F2.0 showed better results when associated with primer.

[**P066-2017**] “The CMS trigger system”

Khachatryan, V.; Sirunyan, A. M.; Chinellato, J. A.*; Tonelli Mangante, E. J.*, et al.

CMS Collaboration

This paper describes the CMS trigger system and its performance during Run 1 of the LHC. The trigger system consists of two levels designed to select events of potential physics interest from a GHz (MHz) interaction rate of proton-proton (heavy ion) collisions. The first level of the trigger is implemented in hardware, and selects events containing detector signals consistent with an electron, photon, muon, tau lepton, jet, or missing transverse energy. A programmable menu of up to 128 object-based algorithms is used to select events for subsequent processing. The trigger thresholds are adjusted to the LHC instantaneous luminosity during data taking in order to restrict the output rate to 100 kHz, the upper limit imposed by the CMS readout electronics. The second level, implemented in software, further refines the purity of the output stream, selecting an average rate of 400 Hz for offline event storage. The objectives, strategy and performance of the trigger system during the LHC Run 1 are described.

[**P067-2017**] “The DarkSide experiment”

Bottino, B.; Aalseth, C. E.; Machado, A. A.*; Segreto, E.*; et al.

DarkSide is a dark matter direct search experiment at Laboratori Nazionali del Gran Sasso (LNGS). DarkSide is based on the detection of rare nuclear recoils possibly induced by hypothetical dark matter particles, which are supposed to be neutral, massive (m > 10 GeV) and weakly interactive (WIMP). The dark matter detector is a two-phase time projection chamber (TPC) filled with ultra-pure liquid argon.
The TPC is placed inside a muon and a neutron active vetoes to suppress the background. Using argon as active target has many advantages, the key features are the strong discriminant power between nuclear and electron recoils, the spatial reconstruction and easy scalability to multi-tons size. At the moment DarkSide-50 is filled with ultra-pure argon, extracted from underground sources, and from April 2015 it is taking data in its final configuration. When combined with the preceding search with an atmospheric argon target, it is possible to set a 90% CL upper limit on the WIMP-nucleon spin-independent cross section of 2.0x10^{-44} cm^2 for a WIMP mass of 100 GeV/c^2. The next phase of the experiment, DarkSide-20k, will be the construction of a new detector with an active mass of similar to 20 tons.

**[P068-2017]** “Theoretical investigation on the magnetostatic interaction between two wire-tube nanostructures”

Riveros, A.; Salazar-Aravena, D.;*; Escrig, J.

In this paper we have calculated analytically the magnetostatic interaction between two wire-tube nanostructures as a function of their magnetic and geometric parameters. As expected, the interaction energy increases as the nanostructures approach, but interestingly when the nanostructures are close enough, a nonmonotonic behavior with the wire-tube portions is reported. Besides, we investigate the hysteresis loop for two interacting Ni81Fe19 wire-tube nanostructures by micromagnetic simulations in order to study how the interaction affects the magnetic properties of these nanostructures. This work allows for the study of magnetostatic interactions between wire-tube nanostructures that have been proposed as an interesting alternative to store information or even perform logic functions, because to their ability to pin a domain wall.

**[P069-2017]** “Transport through hybrid superconducting/ferromagnetic double-path junction”

In this paper we study a double-path junction formed by a ferromagnetic and a superconductor lead. The first path connects the superconductor and ferromagnet directly while the second path connects these metals through a quantum dot. The whole system works as an Aharonov-Bohm interferometer allowing the study of the interference between these two paths under the presence of spin imbalance and Andreev bound states. We considered the effect of Fano interference on the electronic transmittance through the quantum dot and observed two regimes of conduction depending on the strength of the direct coupling. For the weak coupling regime, the transmittance presented the usual four resonances due to the Andreev bound states whereas for the strong coupling regime the profile was inverted and resonances became anti-resonances. However, even in the strong coupling regime it was possible to observe a central resonance due to the interference between the Andreev bound states. We have also studied the signatures of Fano interference on the average occupation within the quantum dot. The spin accumulation was analyzed and how it depends on the direct coupling and an external magnetic field applied to the system. The results obtained may be used in a possible experimental implementation of this system in order to probe spin related effects in ferromagnetic superconductor nanostructures.

**[P070-2017]** “W and Z boson production in p-Pb collisions at TeV root s(NN)=5.02 TeV”

**ALICE Collaboration**

The W and Z boson production was measured via the muonic decay channel in proton-lead collisions at root s(NN) = 5.02 TeV at the Large Hadron Collider with the ALICE detector. The measurement covers backward (4.46 < y(cms) < 2.96) and forward (2.03 < y(cms) < 3.53) rapidity regions, corresponding to Pb-going and p-going directions, respectively. The Z-boson production cross section, with dimuon invariant mass of 60 < m(mu mu) < 120 GeV/c^2 and muon transverse momentum (p(T)(mu)) larger than 20 GeV/c, is measured. The production cross section and charge asymmetry of muons from W-boson decays with p(T)(mu) > 10 GeV/c are determined. The results are compared to theoretical calculations both with and without including the nuclear modification of the parton distribution functions. The W-boson production is also studied as a function of the collision centrality: the cross section of muons from W-boson decays is found to scale with the average number of binary nucleon-nucleon collisions within uncertainties.
